1. a) False
   b) True
   c) True
   d) True

Notes

- **User Mode**
  - Is restricted
  - Executing code has no ability to *directly* access hardware or reference memory [1]
  - Crashes are always recoverable [1]
  - Is where most of the code on our computer / applications are executed [3]
- **Kernel Mode**
  - Is previleged (non-restricted)
  - Executing code has complete and unrestricted access to the underlying hardware [3]
  - Is generally reserved for the lowest-level, most trusted functions of the operating system [1]
  - Is fatal to crash; it will halt the entire PC (i.e the blue screen of death) [3]
- **Interrupt**
  - Are signals sent to the CPU by external devices, normally I/O devices. [2]
  - Tells the CPU to stop its current activities and execute the appropriate part of the operating system (**Interrupt Handler**). [2]
  - Has three different types [2]
    1) **Hardware Interupts**
       * Are generated by hardware devices to signal that they need some attention from the OS.
       * May be due to receiving some data

         Examples

         · Keystrokes on the keyboard
         · Receiving data on the ethernet card

       * May be due to completing a task which the operating system previous requested

         Examples

         Transfering data between the hard drive and memory

2) **Software Interupts**

   * Are generated by programs when a system call is requested

3) **Traps**

   * Are generated by the CPU itself
   * Indicate that some error or condition occured for which assistance from the operating system is needed

- **Content Switch**
  - Is switching from running a user level process to the OS kernel and often to other user processes before the current process is resumed
  - Happens during a timer interrupt or system call
  - Saves the following states for a process during a context switch
    * Stack Pointer
    * Program Counter
    * User Registers
    * Kernel State
  - May hinder performance
- **System Call**

  Example
  - `yield()`
    * Is a system call
    * Causes the calling thread to relinquish the CPU
    * Places the current thread at the end of the run queue
    * Schedules another thread to run
- **Thread**
  - Is a lightweight process that can be managed independently by a schdeduler [4]
  - Improves the application performance using parallelism. (e.g peach)

  - A thread is bound to a single process
  - A process can have multiple threads
  - Has two types
    - **User-level Threads:**
      - Are implemented by users and kernel is not aware of the existence of these threads
      - Are represented by a program counter(PC), stack, registers and a small process control block
      - Are small and much faster than kernel level threads
    - **Kernel-level Threads:**
      - Are handled by the operating system directly
      - Thread management is done by the kernel
      - Are slower than user-level threads

- **Process**
  - Is a program in execution
  - Is named by it's process ID or PID
  - Can be described by the following states at any point in time
    - Address Space
    - CPU Registers
    - Program Counter
    - Stack Pointer
    - I/O Information

    (wait. this is PCB)
  - Exists in one of many different **process states**, including
    1. Running
    2. Ready to Run

3. Blocked

    * Different events (Getting Scheduled, descheduled, or waiting for I/O) transitions one of these states to the other

- **Signals**
  - Provides a way to communicate with the process
  - Can cause job to stop, continue, or terminate
  - Can be delivered to an application
    * Stops the application from whatever its doing
    * Runs Signal handler (some code in application to handle the signal)
    * When finished, the process resumes previous behavior
- **Spinlock**
  -
