Question 1

a. First, we will evaluate the cost of the inner most loop.

Because the loop runs from $j = i + 1$ to $j = n - 1$, with each iteration costing 1 step, we can conclude that the inner most loop has cost of at most

$$\lceil (n - 1) - (i + 1) + 1 \rceil = n - i - 1 \quad (1)$$

steps.

Next, we will evaluate the cost of the outer most loop.

Because the loop runs from $i = 0$ to $i = n - 1$ with each iteration costing $(n - i - 1)$ steps, we can conclude the outer most loop has cost of at most

$$\sum_{i=0}^{n-1} (n - i - 1) = \left[\sum_{i=0}^{n-1} (n - 1) - \sum_{i=0}^{n-1} i \right] \quad (2)$$

$$= \left[\frac{2n(n - 1)}{2} - \frac{(n - 1)n}{2} \right] \quad (3)$$

$$= \frac{n(n - 1)}{2} \quad (4)$$

steps.

Next, we will bring everything together.

Since the lines **n = len(lst)** and **return False** have cost of 1 step each, the total cost of the algorithm is

$$\frac{n(n-1)}{2} + 2 \quad (5)$$

steps.

Then, it follows from above that the algorithm has runtime of $\Theta(n^2)$.

Correct Solution:

First, we will evaluate the cost of the inner most loop.

Because the loop runs from $j = i + 1$ to $j = n - 1$, with each iteration costing 1 step, we can conclude that the inner most loop has cost of at most

$$\lceil (n - 1) - (i + 1) + 1 \rceil = n - i - 1 \quad (6)$$

steps.

Next, we will evaluate the cost of the outer most loop.

Because the loop runs from $i = 0$ to $i = n - 1$ with each iteration costing $(n - i - 1)$ steps, we can conclude the outer most loop has cost of at most

$$\sum_{i=0}^{n-1} (n - i - 1) = \left[\sum_{i=0}^{n-1} (n - 1) - \sum_{i=0}^{n-1} i \right] \quad (7)$$

$$= \left[\frac{2n(n-1)}{2} - \frac{(n-1)n}{2} \right] \quad (8)$$

$$= \frac{n(n-1)}{2} \quad (9)$$

steps.

Next, we will bring everything together.

Since the lines **n = len(lst)** and **return False** have cost of 1 step each, the total cost of the algorithm is **at most**

$$\frac{n(n-1)}{2} + 2 \quad (10)$$

steps.

Then, it follows from above that the algorithm has runtime of $\mathcal{O}(n^2)$.

Notes:

- Noticed that in here, professor considers the cost of loop variables and other lines with constant time.
- \mathcal{O} used since we are determining the upper bound.
- In worksheet 14, the cost of loop variables is not required.

b. Let $n \in \mathbb{N}$, and $lst = [0, 1, 2, 3, \dots, n-3, n-1, n-1]$.

First, we will calculate the cost of the inner most loop.

Because we know the loop will terminate when **if** `lst[i] == lst[j]` and because we know this condition occurs when $i = n-2$, we can conclude the loop will start at $i = 0$ and run until $i = n-2$.

Because we know the inner loop condition **for** `j in range(i+1,n)` stays true until $i = n-2$ even for the worst case, we can conclude that the cost of inner loop is the same as the cost of the inner loop at worst case, that is

$$n - i - 1 \tag{1}$$

Next, we will evaluate the cost of the outer most loop.

Since the outer most loop starts at $i = 0$ and ends at $i = n-1$ with each taking $(n-i-1)$ steps, the outer most loop has cost of

$$\sum_{i=0}^{n-1} (n - i - 1) = \frac{n(n-1)}{2} \tag{2}$$

steps.

Next, we will combine everything together.

Since each of the lines `n = len(lst)` and `return True` have cost of 1 step, we can conclude that the algorithm has total cost of

$$\frac{n(n-1)}{2} + 2 \tag{3}$$

steps.

Then, we can conclude that under this input group, the algorithm has runtime of $\Omega(n^2)$.

Since both $\mathcal{O}(n^2)$ and $\Omega(n^2)$ are true, we can conclude $\Theta(n^2)$ is also true.

Question 2
