Worksheet 15 Solution

March 26, 2020

Question 1

a. **Inner Loop Iterations (upper bound):** n

Inner Loop Step Size: 1

Inner Loop Steps Total: n

Outer Loop Iterations (upper bound): n

Outer Loop Step Size: 1

Outer Loop Steps Total: n

Steps Total: $n \cdot n = n^2$

Correct Solution:

Since the inner loop starts at $i+1$ and ends at $n-1$, where i represents the variable in outer loop, the inner loop has $(n-1-(i+1)+1) = n-i-1$ iterations.

Since each iteration takes 1 step, the total steps taken by inner loop is:

$$(n-i-1) \cdot 1 = (n-i-1) \tag{1}$$

Now, we will evaluate total steps taken by outer loop.

Since the outer loop starts at $i = 0$, and ends at $n - 1$, the loop runs at most n iterations.

Since each iteration takes $(n - i - 1)$ steps, the total steps of outer loop is:

$$
\begin{aligned}
\sum_{i=0}^{n-1}(n - i + 1) &= \sum_{i=0}^{n-1}[(n-1) - i] && (2)\\
&= \sum_{i=0}^{n-1}(n-1) - \sum_{i=0}^{n-1} i && (3)\\
&= n(n-1) - \frac{n(n-1)}{2} && (4)\\
&= \frac{n^2 - n}{2} && (5)
\end{aligned}
$$

Then, since the last **return** statement takes 1 step, it follows that the total number of steps of this algorithm is at most $\frac{n^2-n}{2} + 2$, or $\mathcal{O}(n^2)$.

b. Consider the input family where none of the values in a list are the same (i.e. $[1, 2, 3, 4, 5, 6, 7, 8, 9]$).

Since all values in the input list are not matching, both the inner and the outer loop will run, giving the loops the total number of steps of $\frac{n^2-n}{2}$.

Since the last **return** statement takes 1 step, the total number of steps of this algorithm is $\frac{n^2-n}{2} + 1$, or $\Omega(n^2)$.

<u>**Correct Solution:**</u>

Let $n \in \mathbb{N}$ and $lst = [1, 2, 3, \ldots, n-1, n-1]$.

Since the inner loop will run without interruptions until the end, the inner loop has

$$n - 1 - (i + 1) + 1 = n - i - 1 \tag{1}$$

iterations.

Then, since the inner loop takes 1 step per iteration, the total steps taken by the inner loop is

$$(n - i - 1) \cdot 1 = (n - i - 1) \tag{2}$$

Since the **if condition** $lst[i] == lst[j]$ and the **return** statement are activated when $i = n - 2$, the outer loop will run until $i = n - 2$, where j is the variable of the inner loop and i is the variable of the outer loop.

Since the outer loop starts at 0 and ends at $n - 2$, it has

$$n - 2 + 1 = n - 1 \tag{3}$$

iterations.

Since each iteration in the outer loop takes $(n - i - 1)$ steps, the outer loop has total cost of

$$\sum_{i=0}^{n-2}(n-i-1) = \sum_{i=0}^{n-2}(n-1) + \sum_{i=0}^{n-2} i \tag{4}$$

$$= (n-1)(n-1) - \frac{(n-2)(n-1)}{2} \tag{5}$$

$$= \frac{(n-1)n}{2} \tag{6}$$

Since each of the **if condition** and **return** statement has cost of 1, the total cost of algorithm is $\frac{n(n-1)}{2} + 2$, or $\Omega(n^2)$

c. Let $n \in \mathbb{N}$, and $lst = [1, 2, 3, \ldots, n-1, 1]$

Since the inner loop will run from $j = i + 1$ until the end without interruptions, the loop has

$$(n-1) - (i+1) + 1 = n - i - 1 \tag{1}$$

iterations.

Since the inner loop takes 1 step per iteration, the loop takes total of

$$(n-i-1) \cdot 1 = (n-i-1) \tag{2}$$

steps.

Now, because we know that the **if condition** and **return** statement will occur at $i = 0$, the outer loop has at most 1 iteration.

Because we know that the outer loop terminates at $i = 0$, the total cost of inner loop can be simplified to

$$(n-i-1) = n - 1 \tag{3}$$

Since the outer loop has 1 iteration and takes $n-1$ steps, the loop has total cost of $n-1$.

Lastly, since each of the **if condition** and **return** statement has cost of 1, the total cost of the algorithm is

$$n - 1 + 2 = n + 1 \tag{4}$$

steps, or $\Theta(n)$.

Note

- What's the lower/upper bound of this input family? How can I find them?
- $[1, 2, 3, ..., 1, n-1]$ returns total cost of algorithm of n. Does it imply $[1, 2, 3, ..., 1, n-1]$ is in different input family than $[1, 2, 3, ..., n-1, 1]$?
- $g \in \mathcal{O}(f)$: $\exists c, n_o \in \mathbb{R}^+$, $\forall n \in \mathbb{N}$, $n \geq n_0 \Rightarrow g(n) \leq cf(n)$, where $f, g : \mathbb{N} \to \mathbb{R}^{\geq 0}$
- $g \in \Omega(f)$: $\exists c, n_o \in \mathbb{R}^+$, $\forall n \in \mathbb{N}$, $n \geq n_0 \Rightarrow g(n) \geq cf(n)$, where $f, g : \mathbb{N} \to \mathbb{R}^{\geq 0}$
- $g \in \Theta(f)$: $g \in \mathcal{O}(f) \land g \in \Omega(f)$

Question 2

a. Since $j = len(lst) = n$ and $i = 0$ initially, the initial value of r is

$$\begin{align} r &= j - i \tag{1} \\ &= n - 0 \tag{2} \\ &= n \tag{3} \end{align}$$

b. The loop terminates when $r \leq 0$.

c. Let $k \in \mathbb{N}$, and $j, i \in \mathbb{Z}$. Assume $j > i$.

We will prove the statement by separating into two cases, and combining them at the end.

Case1 $(lst[mid] < x)$:

Assume $lst[mid] < x$.

Then, it follows from the fact $i = \lfloor \frac{i+j}{2} \rfloor + 1$ and $j = j$ that the value of r at $k + 1^{th}$ step is

$$r_{k+1} = j - \left(\left\lfloor \frac{i+j}{2} \right\rfloor + 1 \right) \tag{1}$$

Then,

$$\begin{aligned}
r_{k+1} &\leq j - \left(\left\lfloor \frac{i+j}{2} \right\rfloor \right) &(2)\\
&\leq \frac{2j}{2} - \left(\left\lfloor \frac{i+j}{2} \right\rfloor \right) &(3)\\
&\leq - \left(\left\lfloor \frac{i+j}{2} \right\rfloor + \frac{(-2j)}{2} \right) &(4)\\
&\leq - \left(\left\lfloor \frac{i+j}{2} \right\rfloor + \frac{(-2j)}{2} \right) &(5)\\
&\leq - \left(\left\lfloor \frac{i+j}{2} + \frac{(-2j)}{2} \right\rfloor \right) &(6)
\end{aligned}$$

by using the fact $\forall x \in \mathbb{Z}$, $\forall y \in \mathbb{R}$, $\lfloor x + y \rfloor = x + \lfloor y \rfloor$.

Then,

$$
\begin{aligned}
-\left(\left\lfloor \frac{i+j}{2} + \frac{(-2j)}{2} \right\rfloor\right) &\leq -\left(\left\lfloor \frac{i-j}{2} \right\rfloor\right) && (7)\\
&\leq -\left(\frac{i-j}{2}\right) && (8)\\
&\leq \left(\frac{j-i}{2}\right) && (9)\\
&\leq \frac{1}{2} r_k && (10)
\end{aligned}
$$

Case2 ($lst[mid] > x$):

Assume $lst[mid] \geq x$.

Then, it follows from the fact $i = 1$ and $j = \left\lfloor \frac{i+j}{2} \right\rfloor$ that the value of r at $k + 1^{th}$ step is

$$
r_{k+1} = \left\lfloor \frac{i+j}{2} \right\rfloor - i \tag{11}
$$

$$
\tag{12}
$$

Then,

$$
\left\lfloor \frac{i+j}{2} \right\rfloor - i \leq \left(\frac{i+j}{2}\right) - i \tag{13}
$$

by the fact $\forall x \in \mathbb{R}, \lfloor x \rfloor \leq x < 1 + \lfloor x \rfloor$.

Then,

$$\left(\frac{i+j}{2}\right) \leq \frac{i+j}{2} - \frac{2i}{2} \tag{14}$$
$$\leq \frac{j-i}{2} \tag{15}$$
$$\leq \frac{1}{2}r_k \tag{16}$$

Then, it follows from proof by cases that the statement $r_{k+1} \leq \frac{1}{2}r_k$ is true.

Notes:

- External properties of ceiling and floor
  1. $\forall x \in \mathbb{R},\ 0 \leq x - \lfloor x \rfloor < 1$
  2. $\forall x \in \mathbb{R}^{\geq 0},\ x \geq 4 \Rightarrow (\lfloor x \rfloor)^2 \geq \frac{1}{2}x^2$
  3. $\forall x \in \mathbb{R}^{\geq 0},\ x \geq 4 \Rightarrow \frac{1}{2}x^2 \geq 2x$
  4. $\forall x \in \mathbb{Z},\ \forall y \in \mathbb{R},\ \lfloor x + y \rfloor = x + \lfloor y \rfloor$
