# CSC148 Worksheet 16 Solution

Hyungmo Gu

April 26, 2020

## Question 1

a. The doctests for the base case is

```
"""

>>> nested_list_contains(1,1)

True

>>> nested_list_contains(1,2)

False
"""

7
```

Using this fact, we can write

```
from typing import Union, List
      def nested_list_contains(obj: Union[int, List], item: int) -> bool:
          """Return whether the given item appears in <obj>.
          Note that if <obj> is an integer, this function checks whether
          <item> is equal to <obj>.
6
          >>> nested_list_contains(1,1)
          True
          >>> nested_list_contains(1,2)
10
          False
11
          0.00
12
13
          if isinstance(self, int):
14
              return obj == item
15
16
```

Listing 1: worksheet\_16\_q1a\_solution

b. Consider the following doctest

```
"""

>>> nested_list_contains([4,2,2,[6,5,7,[8]]],8)

True
    """

5
```

Using the base case from question 1.a, and the basic recursive design recipe, we can conclude the algorithm will behave as follows

```
1) 4 \rightarrow 4 == item? \rightarrow False

2) 2 \rightarrow 2 == item? \rightarrow False

3) 2 \rightarrow False

4) [6,5,7,[8]] \rightarrow Recursion

5) 6 \rightarrow 6 == item? \rightarrow False

6) 5 \rightarrow 5 == item? \rightarrow False

7) 7 \rightarrow 7 == item? \rightarrow False

8) [8] \rightarrow Recursion

9) 8 \rightarrow 8 == item? \rightarrow True (function terminates)
```

Now, no new parameters other than *obj* and *item* are required, since

- 1. for the traversing and checking of elements, they are done using the two parameters.
- 2. for bringing the value 'True' to user, it is done by repeatedly ending the recursive function call early with the value
- 3. for brining the value 'False' to user, it is done by returning False at the end.

```
from typing import Union, List
c_1
3
      def nested_list_contains(obj: Union[int, List], item: int) -> bool:
           """Return whether the given item appears in <obj>.
5
           Note that if <obj> is an integer, this function checks whether
           <item> is equal to <obj>.
           >>> nested_list_contains([4,2,2,[6,5,7,[8]]],8)
9
           >>> nested_list_contains([4,2,2,[6,5,7,[8]]],9)
12
           False
           \Pi_{i}\Pi_{j}\Pi_{j}
13
14
           if isinstance(self, int):
15
               return obj == item
           else:
17
                                    ==== (Solution) =====
18
               for sublist in obj:
19
                    result = nested_list_contains(sublist, item)
20
                    if result:
22
```

Listing 2: worksheet\_16\_q1c\_solution

## Question 2

a. The doctests for the base case is

```
1     """
2     >>> first_at_depth(1,2)
3     None
4     """
```

Using this fact, we can write

```
from typing import Union, List, Optional
2
3
4
      def first_at_depth(obj: Union[int, List], d: int) -> Optional[int]:
          """Return the first (leftmost) item in <obj> at depth <d>.
5
          Return None if there is no item at depth <d>.
6
          Precondition: d \ge 0.
          >>> first_at_depth(1,2)
9
          None
10
          0.00
11
12
          if isinstance(obj, int):
              return None
14
```

Listing 3: worksheet\_16\_q2a\_solution

First, we need to write doctests for the function call on input of some complexity.

Consider the following doctests.

```
"""

>>> first_at_depth([1,2,[3,4,[5,6]]],1)

1

>>> first_at_depth([1,2,[3,4,[5,6]]],3)

5

>>> first_at_depth([1,2,[3,4,[5,6]]],4)

None

>>> first_at_depth([[1,2,[3,4,[5,6]]],4)

"""

11
```

Second, we need to write down the relevant recursive calls for each sub-nested-list of input.

The recursive calls for the example  $first\_at\_depth([1,2,[3,4,[5,6]]],3)$  is as follows

- b. 1)  $1 \rightarrow \text{is current\_depth} == 3? \rightarrow \text{False} \rightarrow \text{return None}$ 
  - 2) 2  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  False  $\rightarrow$  return None
  - 3)  $[3,4,[5,6]] \rightarrow \text{Recursion}$ 
    - 4)  $3 \rightarrow \text{is current\_depth} == 3? \rightarrow \text{False} \rightarrow \text{return None}$
    - 5)  $4 \rightarrow \text{is current\_depth} == 3? \rightarrow \text{False} \rightarrow \text{return None}$
    - 6)  $[5,6] \rightarrow \text{Recursion}$ 
      - 7) 5  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  True  $\rightarrow$  return 5
  - 8) Function Terminates with return value 5 until the end of recursion

Finally, we need to think about the extra parameters for each function.

It follows from above that the extra parameter required for this function is *current\_depth*. To add this parameter, we need to change function *first\_at\_depth* from

### Rough Work:

1. Write a doctest for the function call on input of some complexity

First, we need to write a doctest for the function call on input of some complexity

First, we need to write doctests for the function call on input of some complexity.

Consider the following doctests.

2. Write down the relevant recursive calls for each sub-nested-list of input.

Second, we need to write down the relevant recursive calls for each sub-nested-list of input.

Second, we need to write down the relevant recursive calls for each sub-nested-list of input.

The recursive calls for the example  $first\_at\_depth([1,2,[3,4,[5,6]]],3)$  is as follows

- 1) 1  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  False  $\rightarrow$  return None
- 2) 2  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  False  $\rightarrow$  return None
- 3)  $[3,4,[5,6]] \rightarrow \text{Recursion}$ 
  - 4) 3  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  False  $\rightarrow$  return None
  - 5) 4  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  False  $\rightarrow$  return None
  - 6) [5,6]  $\rightarrow$  Recursion
    - 7) 5  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  True  $\rightarrow$  return 5
- 8) Function Terminates with return value 5 until the end of recursion
- 3. Think about the extra parameters for each function.

Finally, we need to think about the extra parameters for each function.

Finally, we need to think about the extra parameters for each function.

It follows from above that the extra parameter required for this function is  $current\_depth$ . To add this parameter, we need to change function  $first\_at\_depth$  from

First, we need to write doctests for the function call on input of some complexity.

Consider the following doctests.

```
"""

>>> first_at_depth([1,2,[3,4,[5,6]]],1)

1

>>> first_at_depth([1,2,[3,4,[5,6]]],3)

5

>>> first_at_depth([1,2,[3,4,[5,6]]],4)

None

>>> first_at_depth([[1,2,[3,4,[5,6]]],4)

"""

1
```

Second, we need to write down the relevant recursive calls for each sub-nested-list of input.

The recursive calls for the example  $first\_at\_depth([1,2,[3,4,[5,6]]],3)$  is as follows

- 1)  $1 \rightarrow \text{is current\_depth} == 3? \rightarrow \text{False} \rightarrow \text{return None}$
- 2) 2  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  False  $\rightarrow$  return None
- 3)  $[3,4,[5,6]] \rightarrow \text{Recursion}$ 
  - 4)  $3 \rightarrow \text{is current\_depth} == 3? \rightarrow \text{False} \rightarrow \text{return None}$
  - 5) 4  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  False  $\rightarrow$  return None
  - 6)  $[5,6] \rightarrow \text{Recursion}$ 
    - 7) 5  $\rightarrow$  is current\_depth == 3?  $\rightarrow$  True  $\rightarrow$  return 5
- 8) Function Terminates with return value 5 until the end of recursion

Finally, we need to think about the extra parameters for each function.

It follows from above that the extra parameter required for this function is *current\_depth*. To add this parameter, we need to change function *first\_at\_depth* from

#### **Correct Solution:**

First, we need to write doctests for the function call on input of some complexity.

Consider the following doctests.

```
"""

>>> first_at_depth([1,2,[3,4,[5,6]]],1)

1

>>> first_at_depth([1,2,[3,4,[5,6]]],3)

5

>>> first_at_depth([1,2,[3,4,[5,6]]],4)

>>> first_at_depth([[1,2,[3]],4,[[5],6]],3)

8

8

"""
```

Second, we need to write down the relevant recursive calls for each sub-nested-list of input.

The recursive calls for the example  $first\_at\_depth([1,2,[3,4,[5,6]]],3)$  is as follows

```
    1) 1 → is d == 0? → False → return None
    2) 2 → is d == 0? → False → return None
    3) [3,4,[5,6]] → Recursion
    4) 3 → is d == 0? → False → return None
    5) 4 → is d == 0? → False → return None
    6) [5,6] → Recursion
    7) 5 → is d == 0? → True → return 5
    8) Function Terminates with return value 5 until the end of recursion
```

o) I direction Tolliniacoop with Toldin Partie o direction on of Toldiniaco

Finally, we need to think about the extra parameters for each function.

It follows from above that we have everything we need to execute the function and the extra parameter is not required.

```
\mathbf{c}_1
      from typing import Union, List, Optional
2
3
      def first_at_depth(obj: Union[int, List], d: int) -> Optional[int]:
4
          """Return the first (leftmost) item in <obj> at depth <d>.
5
          Return None if there is no item at depth <d>.
6
          Precondition: d >= 0.
8
          >>> first_at_depth(1,2)
9
          >>> first_at_depth(1,0)
10
11
          >>> first_at_depth([1,2,[3,4,[5,6]]],1)
